DESCRIPTION

JC14 Rec'd PCT/PTO 13 MAY 2005

BODY FLUID SUCTION AND COLLECTION UNIT

TECHNICAL FIELD

The present invention relates to a portable body fluid suction reservoir used to suck and evacuate body fluid from a wound cavity of a human body to 5 improve the adhesiveness of tissue in the wound cavity, and thereby accelerate recovery.

BACKGROUND ART

Conventionally, it has been known to use a body fluid suction reservoir in order to suck in and 10 evacuate body fluid from a wound cavity of a human body. In this case, one end of a tube is inserted into the wound cavity to evacuate and lead the body fluid, and the other end of the tube is connected to a suction reservoir, whereby the body fluid in the wound cavity 15 is collected and stored in the suction reservoir by negative pressure generated in the suction reservoir.

As a mechanism for generating the negative pressure in the suction reservoir, there have been known a mechanism disclosed in JP-A-57-81346 in which a 20 container with an extensible elastic member built-in (such as a spring, or rubber) is previously compressed, in other words, the elastic member is contracted to previously reduce the internal volumetric capacity, so

that negative pressure is generated in the container due to restoring force of the elastic member to suck in and collect body fluid, and a mechanism disclosed in JP-A-50-84090 and 61-131751 for example, in which an 5 expandable and extensible elastic member (a balloon or a diaphragm, for example) is provided in a rigid container, and is previously expanded by exhausting gas from the rigid container using internal air supply, exhaust, or other dynamic means, so that negative 10 pressure is generated in the container due to contractive force of the elastic member to suck in and collect body fluid.

Since the former mechanism starts to suck in a state where the container is squashed, it is very 15 compact especially at the beginning of the suction in comparison with the latter mechanism, and has an advantage that it is superior in portability because it does not take much space when it is set to a patient. Further, the former mechanism is provided with a lock 20 means for keeping the container in the squashed state and thus, can contribute to reducing the transferring and storing costs thereof. However, since the suction apparatus disclosed in JP-A-57-81346 is made to release the lock means by folding a hinge portion of a plate, 25 there is a possibility that the lock may be easily released due to external force even in a state where the suction apparatus is packaged or baled in transit or storage. Further, since hooks provide on two plates

are configured to engage with each other, which is advantageous in terms of manufacturing cost and space saving, there is a problem that the hooks cannot be locked due to creep deformation after repeated use.

5 DISCLOSURE OF THE INVENTION

The present invention is made to solve the above problem of a conventional body fluid suction reservoir, and its object is to provide a body fluid suction reservoir which has advantages that it is not bulky even if set to a patient and is superior in portability, and in which a lock is not easily released by external force in a state where it is packaged or baled in transit or storage.

In order to achieve the above object, according to a first aspect of the present invention, there is provided a body fluid suction reservoir including a flexible bag, two plates for supporting the bag, a spring put between the two plates, and a lock consisting of a hook, a release part and a member different from the two plates, by which lock the spring is held in a compressed state between the two plates, which held state can be released.

The above described lock may have flexibility. The lock can be held by one of the plates so as to be deformable from a first state in which the hook is engaged with the other plate to a second state in which the hook is not engaged, and the lock is urged

to be in the first state.

The above described hook may be adapted to move in parallel with a surface of the one plate when the lock is deformed from the first state to the second 5 state.

Also, a part of each of the above described plates may protrude in at least two locations around the release part of the lock in a direction opposite to a direction toward which the release part is pressed.

10 An engagement surface of the hook of the above described lock may have a portion protruding toward an engagement surface of the other plate on a tip side thereof, and the engagement face of the other plate may also have a portion protruding toward the 15 engagement surface of the hook on a hole side.

Moreover, two or more of the above described springs may be arranged in a straight line in a longitudinal direction of the body fluid suction reservoir.

20 The above described bag may include a fluid evacuate port, a lid for the fluid evacuate port, and a suspension hole, and the lid for the fluid evacuate port may be provided with a holding part so as to be held by the suspension hole.

25 Further, according to a second aspect of the present invention, there is provides a body fluid suction reservoir including a flexible bag element having a fluid collecting port for taking in body

fluid, a first plate and a second plate arranged in the bag element to face each other, an elastic member disposed between the first and second plates, and a lock body attached to the second plate, in which the

5 lock body has a hook part and an operation part for displacing the lock portion (that is, a release part) so that the hook part is engaged with an engagement surface of the first plate to fix the first and second plates, thereby the elastic member is compressed and

10 held between the first and second plates, and the operation part is operated to displace the hook part in parallel with a surface of the second plate, so that fixing of the first and second plates is released to generate negative pressure in the bag element.

15 The above described lock body may be elastically deformable. Moreover, a part of the lock body can be fixed to the second plate and thus, the operation part may be operated so as to displace at least the hook part in parallel with the surface of the

20 second plate, and the hook part may be adapted to return to an initial position after the operation.

At least one of the first and second plates may have a cutout portion. Accordingly, the operation part may be disposed in the cutout portion or in

25 correspondence with the cutout portion so as to be located inside an outline of the fluid suction reservoir.

The first plate may include a first shell

part forming a part of the outline of the body fluid suction reservoir and a core part provided on a side of the shell part, which faces the second plate.

Moreover, the second plate may include a second shell

5 part forming a part of the outline of the body fluid suction reservoir. In this configuration, at least a part of the lock body is located on a side of the second shell facing the core part and thereby, the elastic member can be compressed and held by the core
10 part and at least the part of the lock body.

In this case, it is possible to make the core part and the lock body harder than the first and second shell parts.

Alternatively, the first plate may include a
15 first shell part forming a part of an outline of the body fluid suction reservoir and a first core part provided on a side of this shell part facing the second plate, and the second plate may include a second shell part forming a part of the outline of the body fluid
20 suction reservoir and a second core part provided on a side of the shell part facing the first plate. The lock body may be attached to the second shell part or second core part, and the hook part is engaged with a surface of the first core part on an opposite side to
25 the second plate (namely, with a hook engagement surface) to lock the first and second plates. Both ends of the elastic member are intervened between the first and second core parts and thereby the elastic

member is held in a compressed state. According to this configuration, it is possible to make the first and second core parts harder than the first and second shell parts and therefore, constitute each part can be 5 made from an appropriate material for each function, which makes possible to broaden the width of material selection.

Moreover, the above described lock body may have at least two hook parts, and the elastic member 10 may be a spring.

The body fluid suction reservoir of the invention may have at least two springs arranged in a straight line between the first and second plates as an elastic member.

15 The bag element may have a fluid evacuate port, a lid for the fluid evacuate port, and a suspension hole, and the lid for the fluid evacuate port may be provided with a holding part for being held by the suspension hole. Alternatively, the bag element 20 may have a holding part attachment hole for holding the holding part, separately from the suspension hole.

Other objects, features, and advantages of the present invention will become more apparent from the following description of embodiments of the present 25 invention in connection with the accompanying drawings.

The present invention is specifically described in accordance with the drawings.

BEST MODE FOR CARRYING OUT THE INVENTION

According to a first embodiment of a body fluid suction reservoir of the present invention, as shown in Fig. 1, a fluid collecting port 5 is attached 15 to pass through a bag 1, such that a drainage tube (not shown) kept in a patient is connected to the port 5. Preferably, the fluid collecting port 5 has a fluid collecting port one way valve 6 so that body fluid collected in the bag 1 does not flow back into a body 20 cavity of the patient. In a similar manner, a fluid evacuate port 7 is provided to pass through the bag 1, and is provided with a lid 8 for the fluid evacuate port to be attached to the fluid evacuate port 7 during suction and collection (Fig. 3). Accordingly, when the 25 suction and the collection are completed, the body fluid is evacuated by removing the fluid evacuate port lid 8 from the fluid evacuate port 7. As is understood

from Figs. 1 and 2, in a state before the suction and the collection of the body fluid, a spring 3, two plates (a first plate 11 and a second plate 12) holding the spring 3 therebetween, and a lock body 4 for 5 locking the two plates in a state in which the spring 3 is compressed are arranged in the bag 1. It should be noted that, in Figs. 1, 3, and 5, a transparent portion of the lock body 4 is made clear by drawing diagonal broken lines. Preferably, two or more of the springs 3 10 are arranged in a straight line in a longitudinal direction of the body fluid suction reservoir. This provides a slim shape, compared to a case of using one spring 3, in order to generate the same suction capacity and the suction pressure and accordingly, it 15 is possible to make the body fluid suction reservoir easily enter a pocket when carrying it.

It is preferable that the spring 3 has a frustum shape, and can be folded up to a thickness one to three times larger than the diameter of a spring 20 material without interference of a wire material of the spring, which realizes space saving in storage. Moreover, by forming the spring 3 into a shape of which winding pitch is gradually widened from a minor diameter side of the frustum to a major diameter side 25 thereof, the non-linear property of the relation between load and deflection is restrained, which is more preferable for preventing suction pressure from being suddenly reduced at the beginning of the suction.

Moreover, as a material of the spring 3, stainless steel which is not readily rust away is preferable. However, since it is not a portion directly contacting with a human body, the material is not restricted as 5 long as the material has elasticity capable of ensuring sufficient suction force.

The lock body 4 is mounted on a surface of the second plate 12 on a side facing the first plate 11 by a well known method so that the lock body 4 can 10 slide only in one direction on the surface. That is, the lock body 4 is held by the second plate 12 so that it can move in parallel with the surface of the plate, for example, it can move in a lateral direction but it is fixed in a vertical direction. The lock body 4 has 15 four hooks 10 aligned in the above described lateral direction, that is, in a direction vertical to the longitudinal direction of the body fluid suction reservoir, and the hooks 10 extends vertically with respect to the surface of the second plate 12 so as to 20 engage with an upward engagement surface 13 (Figs. 6 and 7) formed in a hole 2 of the first plate 11, and thereby the first plate 11 and second plate 12 are locked.

The lock body 4 further includes a release 25 part (or an operation part) 9 provided adjacently to one of the hooks 10. By pushing the release part 9 in the aligned direction of the hooks 10, the lock body 4 is slid (see Fig. 4) so that the first plate 11 and

second plate 12 are unlocked. When the lock is released, the first plate 11 and second plate 12 are pushed by the spring 3 so as to increase the distance therebetween and thereby negative pressure is generated 5 in the body fluid suction reservoir (Figs. 3 to 6).

It is preferable that the first plate 11 and second plate 12 includes portions 31 which protrude in a direction opposite to a direction in which the release part 9 is pushed, in at least two locations 10 around the release part 9 of the lock body 4. In other words, the protruded portions 31 form a cutout portion 32 on the first plate 11 and the second plate 12, and the release part 9 is housed correspondingly to the cutout portion 32. According to the above 15 configuration, even if the body fluid suction reservoir falls to a floor, the protruded portions 31 of the plates contact with the floor firstly. Therefore, load is not directly applied to the release part 9 and therefore, the risk that the locked state is 20 unexpectedly released is greatly reduced.

Moreover, it is preferable that the lock body 4 has flexibility (or elasticity) by which the lock body 4 can be deformed from a state in which the hooks 10 are secured to the first plate 11 as shown in Fig. 2 25 to a state in which the hooks 10 are not secured to the plate 11. On the other hand, the lock body 4 is required to have strength for locking the first plate 11 and the second plate 12 in a state in which the

spring 3 is compressed. Therefore, when forming the lock body 4 as a single component, it is preferable to use high-rigidity engineering plastic, such as polyacetal or the like, as a material of the lock body 5 4. Since the lock body 4 has elasticity, the hooks 10 is adapted to receive force (return force) which urges the hooks 10 in a direction so as to engage with the first plate 11.

Both the first plate 11 and the second plate 10 12 have thin-plate portions 18 (Figs. 5 and 6), and are constituted so as to be bent by the thin-plate portions 18 serving as a fulcrum in accordance with the extension of the spring 3. Also, the lock body 4 has a thin-lock portion 19 which is bent correspondingly to 15 the bend of the thin-plate portions 18. In order to further decrease the risk that the thin-lock portion 19 is cracked, it is preferable to separate the release part 9 from other portions of the lock body 4, that is, to form the structure so as not to include the thin- 20 lock portion 19 by connecting the lock body 4 with the release part 9 like a hinge. Alternatively, it is preferable to use a material which has large breaking elongation and is not easily cracked for the release part 9 having the thin-lock portion 19, and to connect 25 the release part 19 to the lock 4 made of high-rigidity engineering plastic by means of fitting or the like.

Moreover, as shown in Fig. 7, the engagement surface 33 of the hook 10 may contact with the

engagement surface 13 of the first plate 11 in parallel, however, by forming a protruded portion on front ends 20 and 14 of the engagement surfaces 13 and 33 as shown in Fig. 8, the risk of release of the lock 5 body 4 in transit or storage can be further reduced.

As shown in Figs. 1 and 9, a holding part 16 may be provided adjacently to the fluid evacuate port lid 8 to fix the holding part 16 by hooking the holding part 16 to a suspension hole 15 of the bag 1, which is 10 further preferable since the fluid evacuate port lid 8 does not get in the way when evacuating the fluid. Alternatively, as shown in Fig. 16, the bag 1 may have a holding part attachment hole 40 for fixing the holding part 16, in addition to the suspension hole 15.

15 The first plate 11 and the second plate 12 may be connected each other so as to be pivotable by means of a plate connecting member 17.

As a method of using the body fluid suction reservoir of the present invention, firstly, the fluid 20 evacuate port 7 is closed using the fluid evacuate port lid 8 to connect a drainage tube set to a patient to the fluid collecting port 5. Then, as shown in Figs. 3 and 4, the release part 9 of the lock body 4 is inserted toward a center of the fluid suction reservoir 25 to release the engagement of the hooks 10 with the first plate 11. At this stage, force for separating the first plate 11 and the second plate 12 from each other acts therein due to resilience of the spring 3,

so that negative pressure is generated in the bag 1.

By this negative pressure, body fluid of the patient is sucked and collected from a body cavity. After the suction and the collection of the body fluid are

5 completed, the fluid evacuate port lid 8 is opened to discard the waste fluid stored in the bag 1.

Additionally, the lock body 4 may be flexible so that the hooks are urged in a direction (in a right direction in the drawings) to engage with the first

10 plate 11 and thus, it is possible to press the first plate 11 and the second plate 12 to compress the spring 3 to return to the initial state shown Fig. 1 for re-suction.

As a property requested for the first plate 11 and the second plate 12, it is raised that the first plate 11 and the second plate 12 have rigidity (high elastic modulus, creep resistance) for sufficiently resisting the stress of the compressed spring 3 for a long time, and are translucent or transparent for confirming condition and quantity of the contents, and further, it is important that the thin-plate portions 18 are not easily cracked (breaking elongation is large). In view of these requested physical properties, high molecular weight polypropylene is most 25 preferable as a material constituting the first plate 11 and second plate 12 as a single component, respectively.

Figs. 10 to 15 show a second embodiment of

the body fluid suction reservoir of the present invention. The second embodiment is different from the first embodiment in that each of the first plate 11 and the second plate 12 has a shell part made of a material 5 which is comparatively soft and has large breaking elongation. In Figs. 10 to 15, a component similar to that of the first embodiment is indicated by the same reference number.

As is understood from Fig. 11, in the case of 10 the second embodiment, a first plate is constituted by a shell part 41 which serves to hold an outline of the body fluid suction reservoir, and a core part 42 fixed on an inner side of the shell part 41 which core part 42 serves to directly receive the stress of the spring 15 3. The shell part 41 is provided with a thin-plate portion 18 (Fig. 15). The hooks 10 of the lock body 4 are engaged with an upper surface of the core part 42 to lock the first plate and the second plate as with the case of the first embodiment. By using a different 20 component for each function like this, it becomes possible to constitute each part by a material suitable for each function, which makes it possible to broaden the width of material selection.

On the other hand, the second plate 12 is 25 constituted only by a shell part 43 serving to keep the outline of the body fluid suction reservoir so that the lock body 4 attached to the shell part 43 directly supports the spring 3. The lock body 4 of the second

embodiment extends on the second plate over a wide area compared to the case of the lock body 4 of the first embodiment. Accordingly, it is unnecessary to set the hooks 10 in a central portion of the body fluid suction 5 reservoir, and as shown in Fig. 11, it is possible to set two hooks 10 around each spring 3. This structure in which the lock body 4 supports the spring 3 is advantageous because the number of components can be further reduced and the cost can be suppressed.

10 Accordingly, the spring 3 is held by the core part 42 and the lock body 4 in a compressed state.

The engineering plastic having high elastic modulus and creep resistance as used for the first plate 11 and the second plate 12 of the first embodiment is normally crystalline plastic or fiber reinforced plastic which is opaque and has small breaking elongation. However, amorphous plastic which is transparent and has large breaking elongation has small rigidity in general, and thus, it is preferable 15 to use, as a material of the core part 42, engineering plastic such as polyacetal, filler reinforced plastic, fiber reinforced plastic and the like, which have high elasticity and creep resistance, or metal such as aluminum or stainless steel, and to use, as a material 20 of the shell part 41 provided with the thin-plate portion 18, plastic such as polyethylene or polypropylene having transparency and large breaking 25 elongation.

Figs. 16 to 21 show a third embodiment of the body fluid suction reservoir of the present invention. The third embodiment is different from the first embodiment in that a first plate 11 and a second plate 12 are constituted by shell parts 41 and 43 made of a material which is comparatively soft and has large breaking elongation, and hard core parts 42 and 44 fixed on inner surfaces of the shell parts to directly receive the stress of springs 3, respectively. In Figs. 16 to 21, a component similar to that of the first and second embodiments is indicated by the same reference number with those.

As shown in Fig. 17, the first plate is constituted by the shell part 41 serving to keep an outline of the body fluid suction reservoir, and the core part 42 serving to directly receive the stress of the springs 3, and hooks 10 of a lock body 4 are engaged with an upper surface of the core part 42. In the case of the third embodiment, the second plate is also constituted by the shell part 43 serving to keep the outline of the body fluid suction reservoir, and the core part 44 serving to directly receive the stress of the springs 3. In other words, in the case of the third embodiment, the first plate 11 of the first embodiment shown in Fig. 2 is constituted by the shell part 41 and the core part 42, and the second plate 12 of the first embodiment is constituted by the shell part 43 and the core part 44.

Thus, by constituting the first plate and the second plate by completely different components for each function, it is possible to constitute each part by a material suitable for each function, which makes 5 it possible to broaden the width of material selection. That is, in the case of the third embodiment, since the springs 3 are supported by the core parts 42 and 44, it becomes possible that only the core parts 42 and 43 are constitute by a hard material.

10 Accordingly, similarly to the case of the second embodiment, it is preferable to use the engineering plastic such as polyacetal, filler reinforced plastic, fiber reinforced plastic and the like which have high elastic modulus and creep 15 resistance, or metal such as aluminum or stainless steel as a material of the core parts 42 and 44, and to use plastic such as polyethylene or polypropylene having transparency and large breaking elongation as a material of the shell parts 41 and 43.

20 In the case of the third embodiment, since the core parts 42 and 43 support the springs 3, load in a direction vertical to surfaces of the plates does not directly act on the lock body 4 from the spring 3 and thus, it is possible to slide the lock body 4 on the 25 second plate, smoother.

Although the above descriptions are made for embodiments, the present invention is not limited to the embodiments. It is apparent for a person skilled

in the art that the present invention can be modified or corrected within the scope of the spirit and attached claims of the present invention.
